# Prostatakarzinom und PSMA

**PSMA PET scans** are imaging tests that detect prostate cancer and its spread in the body. They use a radioactive substance that targets prostate-specific membrane antigen (PSMA) expressed in prostate cancer.

- 1 Technician injects radioactive substance into patient's arm, which travels through the body to areas that express PSMA
- 2 Patient lies inside a PET scan machine combined with a CT or MRI scanner, which takes pictures of the body
- 3 Doctor can view parts of the body with high levels of PSMA on the scan
- 4 Information from the scan can help make treatment decisions:
  - Rule out if cancer has spread to other body parts
  - Detect prostate cancer return after surgery or radiation
  - Determine eligibility for PSMA-targeting prostate cancer treatment

# PSMA PET Accuracy

- Sind die LK befallen ? Wenn ja wieviele?
